B. Comparison with Vabulas and Snidal's Dataset

In this section, we present descriptive statistics that compare our dataset with Vabulas and Snidal's dataset of informal intergovernmental organizations. We take their most recent version, from "Cooperation under autonomy", published in the *Journal of Peace Research* in 2021.

Vabulas and Snidal create a dataset of 153 IOs, recording IO name, creation year, end year, state membership in 2017, and a few other variables. We carefully checked the names of each IO in their dataset and in ours, renamed IOs as need be, and matched IOs on their names. 74 of 153 (48%) IOs in Vabulas and Snidal's dataset match in ours, which corresponds to 74 of 260 (28%) IOs in our dataset. Since Vabulas and Snidal do not publish time series membership data, we take the membership data from our dataset, and subset it to create two complementary datasets: of matched IOs that appear in both datasets, and unmatched IOs that appear only in our dataset; lacking state-IO-year membership data in Vabulas and Snidal, we can't compare membership patterns over time from their unmatched IOs.

In figure A1, we show the Spearman rank correlation coefficient of state-level counts of IO membership by year for our full dataset and the subset of IOs that match in Vabulas and Snidal. The correlation is positive and strong, ranging from roughly 0.6 to 0.9 over time. The correlation also strengthens over time, likely because the number of IOs operating also increases over time. Clearly, both datasets are capturing some common state-level IO membership trait. Note, the correlation between annual formal IO membership (COW) and our full dataset ranges from roughly 0.6 to 0.7 during this time period.

In figure A2, we plot states' counts of annual membership in both datasets (Vabulas and Snidal on the horizontal axis; ours on the vertical axis). Our dataset always counts higher membership mechanically, given that only matched IOs from Vabulas and Snidal enter our measures. Membership counts are highly correlated across both IO lists.

Finally, in figure A3, we plot the median number of member states in matched (blue filled circles) and unmatched (black hollow diamonds) IOs over time. Both subsets have similar median IO membership statistics across years, and they become more closely related in later years when the data overlaps more consistently as there are more IOs.

Figure A1. Correlation of states' informal IO membership for authors' dataset and Vabulas and Snidal's by year

Figure A2. Scatterplot comparison of states' informal IO membership for authors' dataset and Vabulas and Snidal's in four years

Figure A3. Median number of member states in informal IO membership for authors' dataset and Vabulas and Snidal's by year
